A. Congruent distribution. In the realm of nonparametric statistics, the relative differences, or orders, of robust estimators are of primary importance. A key implication of this principle is that when there is a shift in the parameters of the underlying distribution, all nonparametric estimates should asymptotically change in the same direction, if they are estimating the same attribute of the distribution. If, on the other hand, the mean suggests an increase in the location of the distribution while the median indicates a decrease, a contradiction arises. It is worth noting that such contradiction is not possible for any LL-statistics in a location-scale 11 distribution, as explained in the previous article on semipara-12 metric robust mean. However, it is possible to construct 13 counterexamples to the aforementioned implication in a shapescale distribution. In the case of the Weibull distribution, 15 its quantile function is $Q_{Wei}(p) = \lambda(-\ln(1-p))^{1/\alpha}$, where $0 \le p \le 1, \ \alpha > 0, \ \lambda > 0, \ \lambda$ is a scale parameter, α is a 17 shape parameter, ln is the natural logarithm function. Then, 18 $m = \lambda \sqrt[\alpha]{\ln(2)}, \ \mu = \lambda \Gamma \left(1 + \frac{1}{\alpha}\right), \text{ where } \Gamma \text{ is the gamma func-}$ 19 tion. When $\alpha = 1$, $m = \lambda \ln(2) \approx 0.693\lambda$, $\mu = \lambda$, when $\alpha = \frac{1}{2}$, $m = \lambda \ln^2(2) \approx 0.480\lambda$, $\mu = 2\lambda$, the mean increases as α 21 changes from 1 to $\frac{1}{2}$, but the median decreases. Previously, 22 the fundamental role of quantile average and its relation to 23 nearly all common nonparametric robust location estimates were demonstrated by using the method of classifying dis-25 tributions through the signs of derivatives. To avoid such scenarios, this method can also be used. Let the quantile average function of a parametric distribution be denoted as QA $(\epsilon, \gamma, \alpha_1, \dots, \alpha_i, \dots, \alpha_k)$, where α_i represent the parameters 29 of the distribution, then, a distribution is γ -congruent if and 30 only if the sign of $\frac{\partial QA}{\partial \alpha_i}$ remains the same for all $0 \le \epsilon \le \frac{1}{1+\gamma}$. 31 If $\frac{\partial QA}{\partial \alpha}$ is equal to zero or undefined, it can be considered both 32 positive and negative, and thus does not impact the analysis. 33 A distribution is completely γ -congruent if and only if it is 34 γ -congruent and all its central moment kernel distributions are also γ -congruent. Setting $\gamma = 1$ constitutes the definitions of congruence and complete congruence. Replacing the QA 37 with γm HLM gives the definition of γ -U-congruence. Cheby-38 shev's inequality implies that, for any probability distributions 39 with finite second moments, as the parameters change, even if some LL-statistics change in a direction different from that 41 of the population mean, the magnitude of the changes in the 42 LL-statistics remains bounded compared to the changes in the population mean. Furthermore, distributions with infinite moments can be γ -congruent, since the definition is based on the quantile average, not the population mean.

The following theorems show the conditions that a distribution is congruent or γ -congruent.

Theorem A.1. A γ -symmetric distribution is always γ -congruent and γ -U-congruent.

Proof. As shown in RSSM I, Theorem .2, for any γ -symmetric distribution with a finite second moment, all quantile averages coincide. Also, according to Theorem .18, all γm HLMs conincide. The conclusion follows immediately.

Data Availability. Data for Table ?? are given in SI Dataset S1. All codes are attached.
